

Jesse Arsola forwarded me this picture of his buddy with a "see through" trout. Looking closely at the picture, you can tell the fish is basically transparent, because the angler's hand can be seen through the body of the fish. Obviously, some pigment is present in the fish, because it has dots, like a normal trout would. The skin and flesh of the fish seem to be lacking pigment otherwise. I've never seen a trout like this one. Was wondering if any of you who might be reading this have observed such a phenomenon. The angler didn't retain the fish, so I don't have any more information about it other than this picture.
